

# ARRAYS

**PROF. NAVRATI SAXENA**

# ARRAYS

- Set of finite homogeneous elements
- It means an array can contain one type of data only
  - Either all integer, or all character
- The elements of array will always be stored in the consecutive (continues) memory location

# Array Format

- Elements of an array can be integers, floats, characters etc.
- All the elements share a common name with an index called subscript.
- In an array of n elements:

# Arrays in C

- **Declaration:** `int arr[10];`
- **int:** data type or type of elements the array will store
- **arr:** Name of the array
- **[10]:** Size or length of array; Number of elements an array can store
- **Read an array in C:** read / write through loops – Defining the array

```
for(i=0; i<=9; i++)
{
    scanf("%d", &arr[i]);
    printf("%d", arr[i]);
}
```

# Advantages of Array

- Represents multiple data items using single name
- Implement other data structures like stacks, queues, tree, etc.
- Two-dimensional arrays are used to represent matrices.
- Many databases include one-dimensional arrays whose elements are records.

# Disadvantages of Array

- Must know in advance the number elements to be stored
- Static structure
  - Fixed size
  - Allocated memory cannot be increased or decreased
  - If we allocate more memory than required; memory space will be wasted
  - If we allocate less memory then our elements can't be stored
- Elements stored in consecutive memory locations
  - Insertion and deletion: difficult and time consuming

# Represent a Linear Array in Memory

**Linear Array A**

|   |      |      |
|---|------|------|
| 0 | 50   | 3000 |
| 1 | 300  | 3002 |
| 2 | 10   | 3004 |
| 3 | 1000 | 3006 |
| 4 | 401  | 3008 |

Base Address  
↙

**Index                      Value                      Address (in Bytes)**

**Consecutive memory locations**

# Declaration

- When declaring arrays, specify
  - **Data type** of array ( integers, floats , characters.....)
  - **Name** of the array.
  - **Size**: number of elements

**array\_type** **array\_name**[**size**];

- Example:
  - **int student[10];**
  - **float my\_array [300];**

# Example

- For example,  
    `int p[ 4 ] ;`  
                    ↗ **Square bracket**
- An array of integers of 4 elements.
- **Starting memory address is determined by the operating system** (just like simple variable).
- Contiguous memory locations are allocated.

# Examples

- Integer array of 10 elements:

```
int arr_1 [10];
```

- Character array of 500 elements:

```
char arr_2 [500];
```

- Float array of 1000 elements:

```
float arr_3 [1000];
```

# Size of an Array

- Amount of storage required to hold an array is directly related to its data type and the size.

- **Example**

Total size in bytes for a 1 D array:

$$\text{total bytes} = \textit{sizeof(data type)} * \textit{size of array}$$

- **int a[7] ;**

$$\begin{aligned}\text{total\_bytes} &= 2 * 7 \text{ (one integer needs 2 bytes of storage)} \\ &= 14 \text{ bytes in memory}\end{aligned}$$

# Sample Exercise

```
int main( ) {  
    float fp_number[20] ;  
    char character[20] ;  
    printf(“%d”, sizeof(fp_number));  
    printf(“%d”, sizeof(character));  
    return(0);  
}
```

## Output:

- 80
- 20

# Initializing arrays

- Array elements must be initialized at time of declaration
  - Otherwise they may contain garbage values
- Initialization can be done either at compile time or run time

# Compile Time Initialization (1/2)

- Initialize elements of array in same way as any other ordinary variables at time of declaration
- Example: `int num[3] = {1,1,1};`
  - All three elements of integer array num is initialized to the same value 1
- `float fl_num[5] = {1.0, 12.50, 100.35};`
  - First three elements of array total will be initialized;
  - Rest two will be initialized to 0.
- If initializer list exceeds size of array, it will produce compiler error

# Compile Time Initialization (2/2)

- `float fl_num[5] = {1.0, 12.50, 100.35};`
- All individual array elements that are not assigned explicit initial values will automatically be set to zero.
- |                              |                                |                                 |
|------------------------------|--------------------------------|---------------------------------|
| <code>fl_num[0] = 1.0</code> | <code>fl_num[1] = 12.50</code> | <code>fl_num[2] = 100.35</code> |
| <code>fl_num[3] = 0.0</code> | <code>fl_num[4] = 0.0</code>   |                                 |

# Initializing Integer arrays

- Another way of initializing the elements of the array is:

```
int num[ ] = {5, 10, -20, 0, 1000} ;
```

- The array size need not be specified explicitly when initial values are included as a part of array declaration.
- Array size will automatically be set equal to the number of initial values specified with in definition.

# Initializing Arrays

The second way is to Initialize each array element separately

```
num[0] = 5;
```

```
num[1] = 10;
```

```
num[2] = -20;
```

```
num[3] = 0;
```

```
num[4] = 1000;
```

# Run time Initialization

- Explicitly initializing an array at run time
- Normally used for large array size
- **Example:**

```
for(i=0; i<100; i++)  
{  
    if(i < 50)  
        num[i] = 0;  
    else  
        num[i] = 1;  
}
```

# Basic operations of Arrays

- **Traversing**
- **Insertion**
- **Deletion**
- **Searching**
- **Sorting**
- **Merging**

# Traversing Arrays

Reading / accessing the elements of the array

|            |            |            |            |            |
|------------|------------|------------|------------|------------|
| <b>[0]</b> | <b>[1]</b> | <b>[2]</b> | <b>[3]</b> | <b>[4]</b> |
| <b>100</b> | <b>200</b> | <b>300</b> | <b>400</b> | <b>500</b> |

|                |              |
|----------------|--------------|
| <b>num [0]</b> | <b>= 100</b> |
| <b>num [1]</b> | <b>= 200</b> |
| <b>num [2]</b> | <b>= 300</b> |
| <b>num [3]</b> | <b>= 400</b> |
| <b>num [4]</b> | <b>= 500</b> |

**ALGORITHM: Traversal(A, LB, UB)**

A is the array with Lower Bound LB and Upper Bound UB

Step 1: for i = LB to UB do

Step 2:     process/read/access A[i]

Step 3: end for loop

# Insertion into Array

Add a new data item in the given collection of data items.

| [0] | [1] | [2] | [3] | [4] |
|-----|-----|-----|-----|-----|
| 100 | 200 | 300 | 400 | 500 |

**Assume:** New element to be inserted is 700 at location/index 2. Shift all the elements from 2<sup>nd</sup> (last) location to the 4<sup>th</sup> location upwards by 1 place. Then insert 700 at the 2<sup>nd</sup> location.

700

**ALGORITHM:** Insert(Arr, N, Item, index)  
A: array with N elements; Item: item to be inserted at position=index

Step 1: for i = N-1 down to index

Step 2: Arr[i+1] ← Arr[i]

Step 3: Arr[index] ← Item

Step 4: N ← N+1

# Deletion from Array

To delete an existing data item from the given collection of data items.

Let  $A[5] = 100, 200, 300, 400, 500$

Delete item 300 from index 2

Let Item = 300

Shift 400 to index 2; 500 to index 3

|      |     |      |     |      |     |      |     |
|------|-----|------|-----|------|-----|------|-----|
| A[0] | 100 | A[0] | 100 | A[0] | 100 | A[0] | 100 |
| A[1] | 200 | A[1] | 200 | A[1] | 200 | A[1] | 200 |
| A[2] | 300 | A[2] |     | A[2] | 400 | A[2] | 400 |
| A[3] | 400 | A[3] | 400 | A[3] |     | A[3] | 500 |
| A[4] | 500 | A[4] | 500 | A[4] | 500 | A[4] |     |

**ALGORITHM:** Delete (Arr, N, Item, index)

Arr is the array with N elements; Item is to be deleted from position = index

Step 1: Item  $\leftarrow$  Arr[index]

Step 2: for i = index down to N-1

Step 3:       Arr[i]  $\leftarrow$  Arr[i+1]

Step 4: N  $\leftarrow$  N-1

# Searching in Arrays

To find out the location of an data item if it exists in the array

| [0] | [1] | [2] | [3] | [4] |
|-----|-----|-----|-----|-----|
| 150 | 500 | 350 | 200 | 250 |

To search item **200**

1. Start from the beginning
2. Compare 200 with each item of the array until
  1. 200 is found or end of array is met

# Linear/Sequential Search

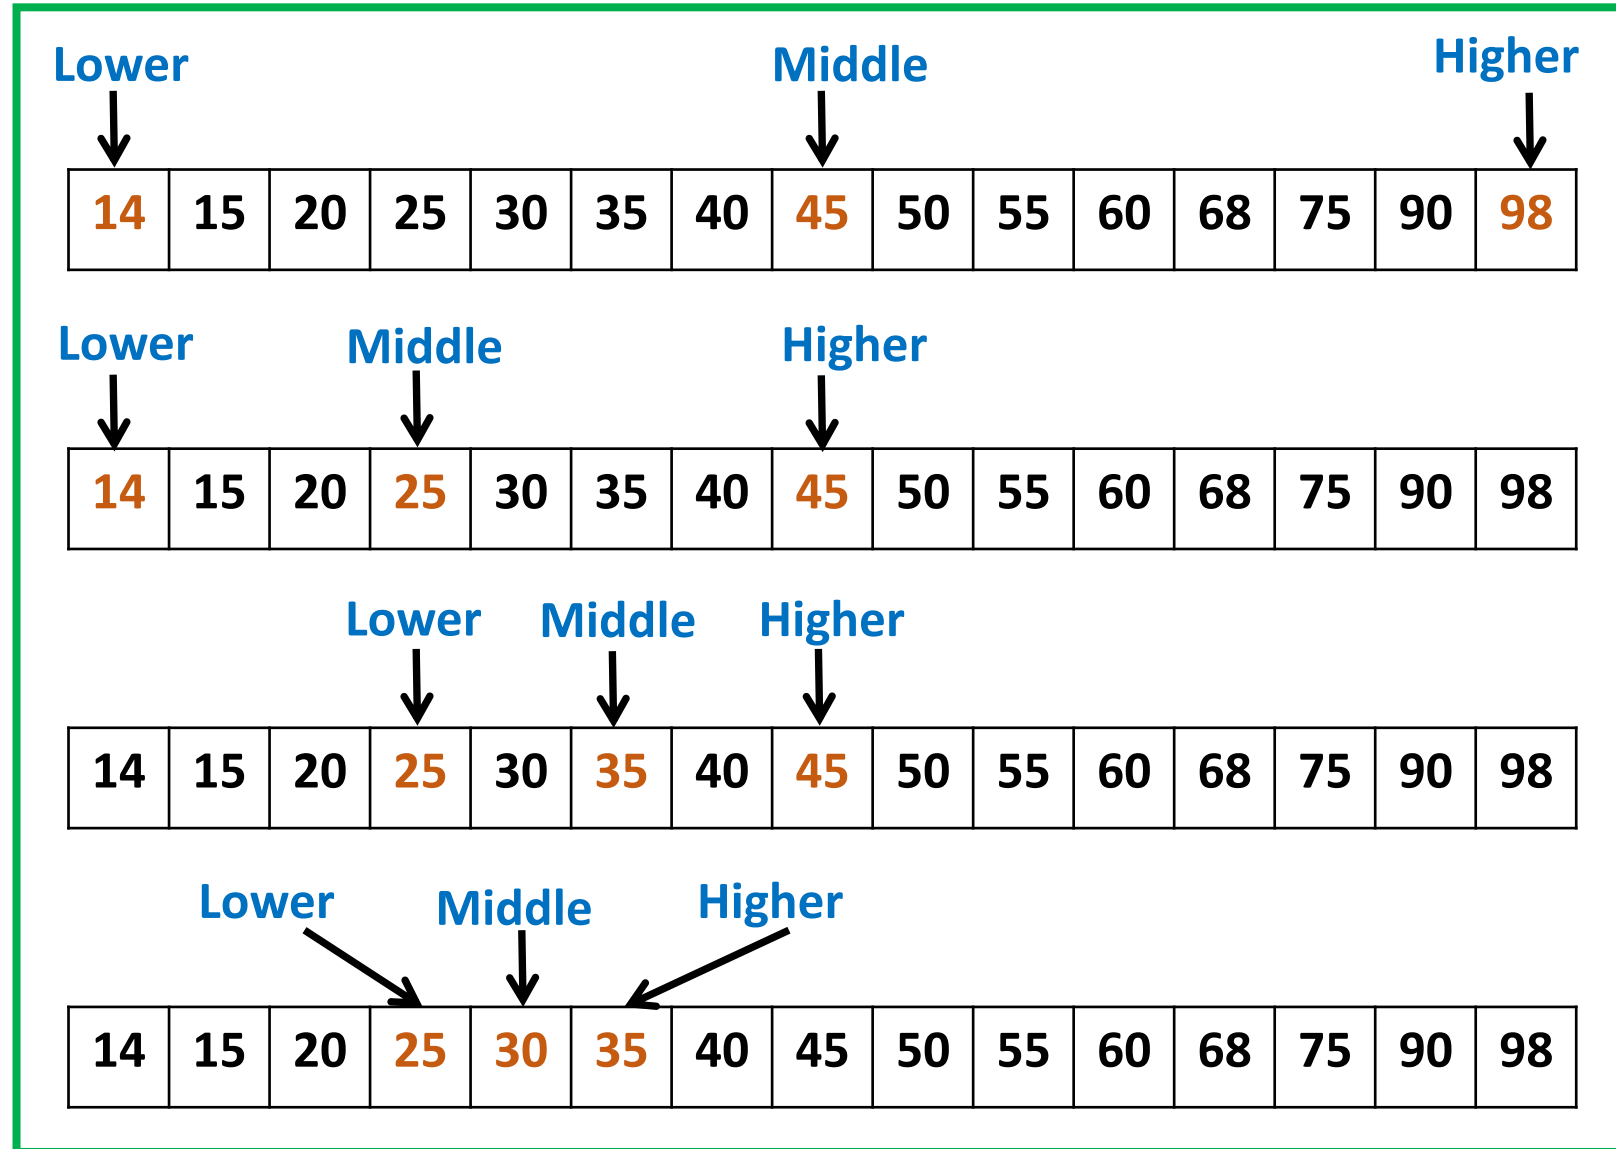

**INPUT: array, item**

- 1. *Begin***
- 2. *Set  $i \leftarrow 0$***
- 3. *Repeat steps 4 and 5 while  $i < N$***
- 4. *if (array[i] = item)***
- 5.     *print i, item***
- 6.  *$i \leftarrow i+1$***
- 7. *End***

# Binary Search

- Sort the array
- Divides the array into two smaller sub-arrays
- Recursively operate the sub-arrays.
- Reduces the search space to half at each step

# Binary Search Algorithm

// A iterative binary search procedure. It returns location of item in given array arr[low..high] if present, otherwise it returns: -1

```
int binarySearch (int arr[], int lower, int higher, int item)
{
    while (lower <= higher)
    {
        mid = lower + (higher - lower) / 2;
        if (arr[mid] == x)                //Check if x is present at mid
            return mid;
        if (arr[mid] < x)
            lower = mid + 1;              // If x greater, ignore left half
        else
            higher = mid - 1;             // If x is smaller, ignore right half
    }
    return -1;                           // if we reach here, then element is not present
}
```

|   | <b>Linear Search</b>                                   | <b>Binary Search</b>  |
|---|--|---|
| 1 | This can be used in sorted and unsorted array          | This can be used in only in sorted array                          |
| 2 | Array elements are accessed sequentially               | One must have direct access to the middle element in the sub list |
| 3 | Slow   | Faster  |
| 4 | This can be used in single and multi dimensional array | Used only in single dimensional array                             |
| 5 | This technique is easy and simple in implementing      | Complex in operation  |

# Sorting

- Arrangement of the elements of the array in some order
  - Numeric array – ascending or descending order
- Different sorting methods
  - Bubble sort
  - Selection sort
  - Shell sort
  - Quick sort
  - Heap sort
  - Insertion sort

# Merging from Array (1/2)

Combine the data items of two sorted arrays

|                |     |     |     |     |     |     |
|----------------|-----|-----|-----|-----|-----|-----|
| <b>Array X</b> | [1] | [2] | [3] | [4] | [5] | [6] |
|                | 20  | 50  | 60  | 90  | 105 | 110 |

|                |     |     |     |     |
|----------------|-----|-----|-----|-----|
| <b>Array Y</b> | [1] | [2] | [3] | [4] |
|                | 30  | 45  | 55  | 100 |

**Merged Array**

|     |     |     |     |     |     |     |     |     |      |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|------|
| [1] | [2] | [3] | [4] | [5] | [6] | [7] | [8] | [9] | [10] |
| 20  | 30  | 45  | 50  | 55  | 60  | 90  | 100 | 105 | 110  |

# Merging from Array (2/2)

## Algorithm

1. Create an array  $Z[]$  of size = size of  $(X)$  + size of  $(y)$
2. Simultaneously traverse  $X[]$  and  $Y[]$ 
  - Pick smaller of current elements in  $X[]$  and  $Y[]$
  - Copy this element to next position in  $Z[]$
  - Move ahead in  $Z[]$  and the array whose element is picked
3. If there are remaining elements in  $X[]$  or  $Y[]$ , copy them also in  $Z[]$

# Types of Arrays

- Single Dimension Array
  - Array with one subscript
- Two Dimension Array
  - Array with two subscripts (Rows and Column)
- Multi Dimension Array
  - Array with Multiple subscripts

# Two dimensional array

- Each element is identified by a pair of subscripts ( num[m] [n] )
  - m = row; n = column
- The elements are stored in continuous memory locations
- Order of the matrix
  - Number of rows and columns in the matrix
  - Denoted as  $m \times n$
- Number of elements in the array = number of rows X number of columns.

|        | num[0] | num[1] | num[2] |
|--------|--------|--------|--------|
| num[0] | 10     | 20     | 30     |
| num[1] | 40     | 50     | 60     |
| num[2] | 70     | 80     | 90     |

```
num[2][3]
for(i=0; i<2; i++)
    for(j=0; j<3; j++)
        print num[i][j]
```

# Two-dimensional Array: Row-major Method

- All the first-row elements are stored in sequential memory locations
- Then all the second-row elements are stored and so on. Ex: A[Row][Col]

|       |            |           |
|-------|------------|-----------|
| 10000 | <b>100</b> | num[0][0] |
| 10002 | <b>200</b> | num[0][1] |
| 10004 | <b>300</b> | num[0][2] |
| 10006 | <b>400</b> | num[1][0] |
| 10008 | <b>500</b> | num[1][1] |
| 10010 | <b>600</b> | num[1][2] |
| 10012 | <b>700</b> | num[2][0] |
| 10014 | <b>800</b> | num[2][1] |
| 10016 | <b>900</b> | num[2][2] |

# Two-dimensional Array: Column-major Method

- All the first column elements are stored in sequential memory locations
- Then all the second- column elements are stored and so on. Ex: A [Col][Row]

|       |            |           |
|-------|------------|-----------|
| 10000 | <b>100</b> | num[0][0] |
| 10002 | <b>200</b> | num[1][0] |
| 10004 | <b>300</b> | num[2][0] |
| 10006 | <b>400</b> | num[0][1] |
| 10008 | <b>500</b> | num[1][1] |
| 10010 | <b>600</b> | num[2][1] |
| 10012 | <b>700</b> | num[0][2] |
| 10014 | <b>800</b> | num[1][2] |
| 10016 | <b>900</b> | num[2][2] |

# How will you store a table or matrix?

|       | Item1 | Item2 | Item3 |
|-------|-------|-------|-------|
| Shop1 | 1310  | 1275  | 1365  |
| Shop2 | 1210  | 1190  | 1325  |
| Shop3 | 1405  | 1235  | 1240  |
| Shop4 | 1260  | 1300  | 1380  |

Store this data, create 2-D array : `int arr[4][3];`

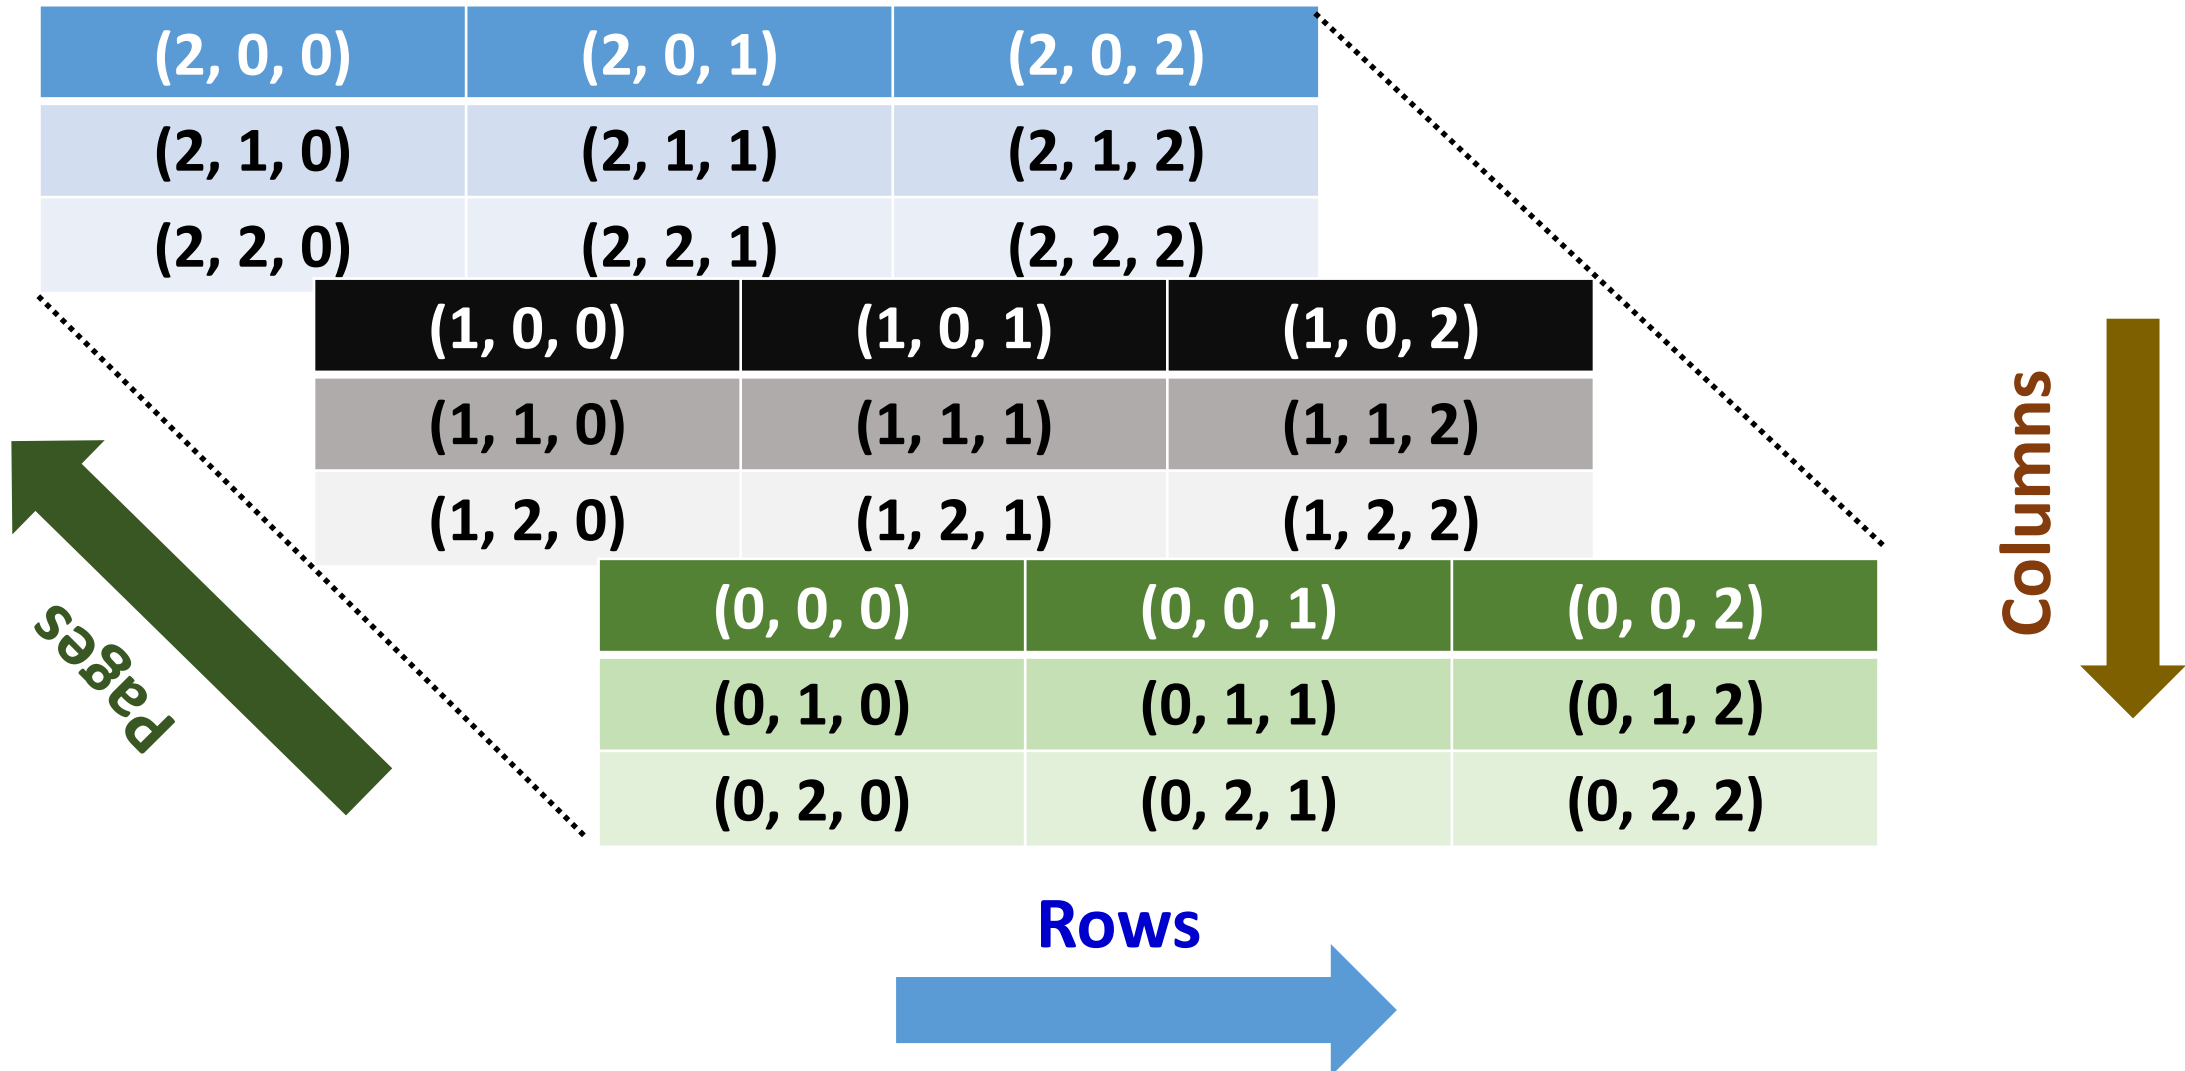

`(data type) array_name[# of rows] [# of columns];`

# Multidimensional Arrays

- Arrays with two or more dimensions
- In a three dimensional array:
  - The first dimension is called a plane - consists of rows and columns.
  - C language considers the three-dimensional array to be an array of two-dimensional arrays.

# C View of Three-dimensional Array

# DISADVANTAGE OF ARRAYS

- Static memory allocation
- Maximum size reserved in advance
  - Problems of Less Resource Utilization
- Different data types could not be stored in an array

**Thank you!**
